Kubernetes - Workshop

This is just an intro, which tights to the presentation of Modern Application. For this workshop we will leverage kind.
Kind is a tool for running local Kubernetes clusters using Docker container “nodes”. kind was primarily designed for testing Kubernetes itself, but may be used for local development or CI.

We will first build a simple cluster with a specific name. If you omit the flag --name default name will be kind. As we get a little more familiar with kind cli, keep in mind that the other tool we could have selected was minikube, however, kind is newer and allows you to run a small kubernetes cluster for testing and learning purposes.

Shotcut your typing

```
echo  "alias k=kubectl" >>~/.bashrc
```

Understand how to use help with kubectl. Each main subcommand has a subset of help. The main will be kubectl -h or kubectl --help. Of course, this workshop is not going through each of the commands, that's something you can explore in your own. We will however cover many of them.

Show Merged kubeconfig settings.

```
kubectl config view
```

Use multiple kubeconfig files at the same time and view merged config

```
KUBECONFIG=~/.kube/config:~/.kube/kubconfig2
```

```
kubectl config view
```

Display list of contexts

```
kubectl config get-contexts
```

Display the current-context

```
kubectl config current-context
```

Set the default context to my-cluster-name, the name can be showed with the command above.

```
kubectl config use-context <<cluster-name>>
kubectl config set-context kind-remo
kubectl config -h <to get some additional help>
```

EXAMPLE: (in my case I have two running, KIND and Minikube, and it shows you which is the default config)

```
kubectl config get-contexts
CURRENT   NAME        CLUSTER     AUTHINFO    NAMESPACE
*         kind-kind   kind-kind   kind-kind
          minikube    minikube    minikube    default
```

Add a new user to your kubeconf that supports basic auth. We use this example in our Agility Lab, which was offered the last couple of years. CIS Lab

```
kubectl config set-credentials kubeuser/foo.kubernetes.com --username=kubeuser
--password=kubepassword
```

Permanently save the namespace for all subsequent kubectl commands in that context.

```
kubectl config set-context --current --namespace=ciao
```

Set a context utilizing a specific username and namespace.

```
kubectl config set-context gce --user=cluster-admin --namespace=ciao \
  && kubectl config use-context gce
```

This unsets the config for the user ciao kubectl config unset users.ciao

Single Cluster

First let's evaluate kind's help

```
kind --help
kind creates and manages local Kubernetes clusters using Docker container 'nodes'

Usage:
  kind [command]

Available Commands:
  build       Build one of [node-image]
  completion  Output shell completion code for the specified shell (bash, zsh or fish)
  create      Creates one of [cluster]
  delete      Deletes one of [cluster]
  export      Exports one of [kubeconfig, logs]
  get         Gets one of [clusters, nodes, kubeconfig]
  help        Help about any command
  load        Loads images into nodes
  version     Prints the kind CLI version

Flags:
  -h, --help              help for kind
      --loglevel string   DEPRECATED: see -v instead
  -q, --quiet             silence all stderr output
  -v, --verbosity int32   info log verbosity
      --version           version for kind

Use "kind [command] --help" for more information about a command.
```

```
kind create cluster --name workshop
```

OUTPUT:

```
 kind create cluster --name workshop
Creating cluster "workshop" ...
  Ensuring node image (kindest/node:v1.20.2) 
  Preparing nodes 
  Writing configuration 
  Starting control-plane 
  Installing CNI 
  Installing StorageClass 
Set kubectl context to "kind-workshop"
You can now use your cluster with:

kubectl cluster-info --context kind-workshop

Have a nice day! 
```

Using kind command to verify we have a cluster

```
 kind get clusters
```

OUTPUT:

```
 kind get clusters
workshop
```

Check nodes

```
 kubectl get nodes
```

OUTPUT: We can see the workshop name for the control plane.

```
 k get nodes
NAME                     STATUS   ROLES                  AGE   VERSION
workshop-control-plane   Ready    control-plane,master   11m   v1.20.2
```

We will use the describe subcommand to see the details of the node.

```
 kubectl describe no <<your node name>>
```

Example:

```
 kubect describe no workshop-control-plane
```

NOTE the option no is short for nodes.

OUTPUT:

```
 kubectl describe no workshop-control-plane
Name:               workshop-control-plane
Roles:              control-plane,master
Labels:             beta.kubernetes.io/arch=amd64
                    beta.kubernetes.io/os=linux
                    kubernetes.io/arch=amd64
                    kubernetes.io/hostname=workshop-control-plane
                    kubernetes.io/os=linux
                    node-role.kubernetes.io/control-plane=
                    node-role.kubernetes.io/master=
Annotations:        kubeadm.alpha.kubernetes.io/cri-socket:

```

Delete the current kind cluster. If you have the default cluster, named **kind**, you do not have to use the --name option.

```
kind delete cluster --name workshop
```

OUTPUT:

```
 kind delete cluster --name workshop
Deleting cluster "workshop" ...
```

Create a cluster with 3 workers. create a file, called mykind with the directions below:

```
 vi mykind
```

Directives for the file mykind. This will build the control plane and 3 workers node.

```
kind: Cluster
apiVersion: kind.x-k8s.io/v1alpha4
# One control plane node and three "workers".
#
# While these will not add more real compute capacity and
# have limited isolation, this can be useful for testing
# rolling updates etc.
#
# The API-server and other control plane components will be
# on the control-plane node.
#
# You probably don't need this unless you are testing Kubernetes itself.
nodes:
- role: control-plane
- role: worker
- role: worker
- role: worker
```

To build the new cluster with 3 workers and 1 control-plane execute the following:

```
kind create cluster --config mykind
```

OUTPUT:

```
 kind create cluster --config mykind
Creating cluster "kind" ...
 Ensuring node image (kindest/node:v1.20.2) 
 Preparing nodes    
 Writing configuration 
 Starting control-plane 
 Installing CNI 
 Installing StorageClass 
 Joining worker nodes 
Set kubectl context to "kind-kind"
You can now use your cluster with:

kubectl cluster-info --context kind-kind

Thanks for using kind! 
```

Check nodes

```
 kubectl get nodes
```

OUTPUT: We can see the workshop name for the control plane.

```
 k get nodes
NAME                 STATUS   ROLES                  AGE     VERSION
kind-control-plane   Ready    control-plane,master   2m35s   v1.20.2
kind-worker          Ready    <none>                 2m4s    v1.20.2
kind-worker2         Ready    <none>                 2m4s    v1.20.2
kind-worker3         Ready    <none>                 2m4s    v1.20.2
```

OUTPUT: with the wide option

As you recall from our docker section, we will check how many containers are running in docker.

```
 docker ps
```

OUTPUT:

```
 docker ps
CONTAINER ID   IMAGE                  COMMAND                  CREATED         STATUS
PORTS                       NAMES

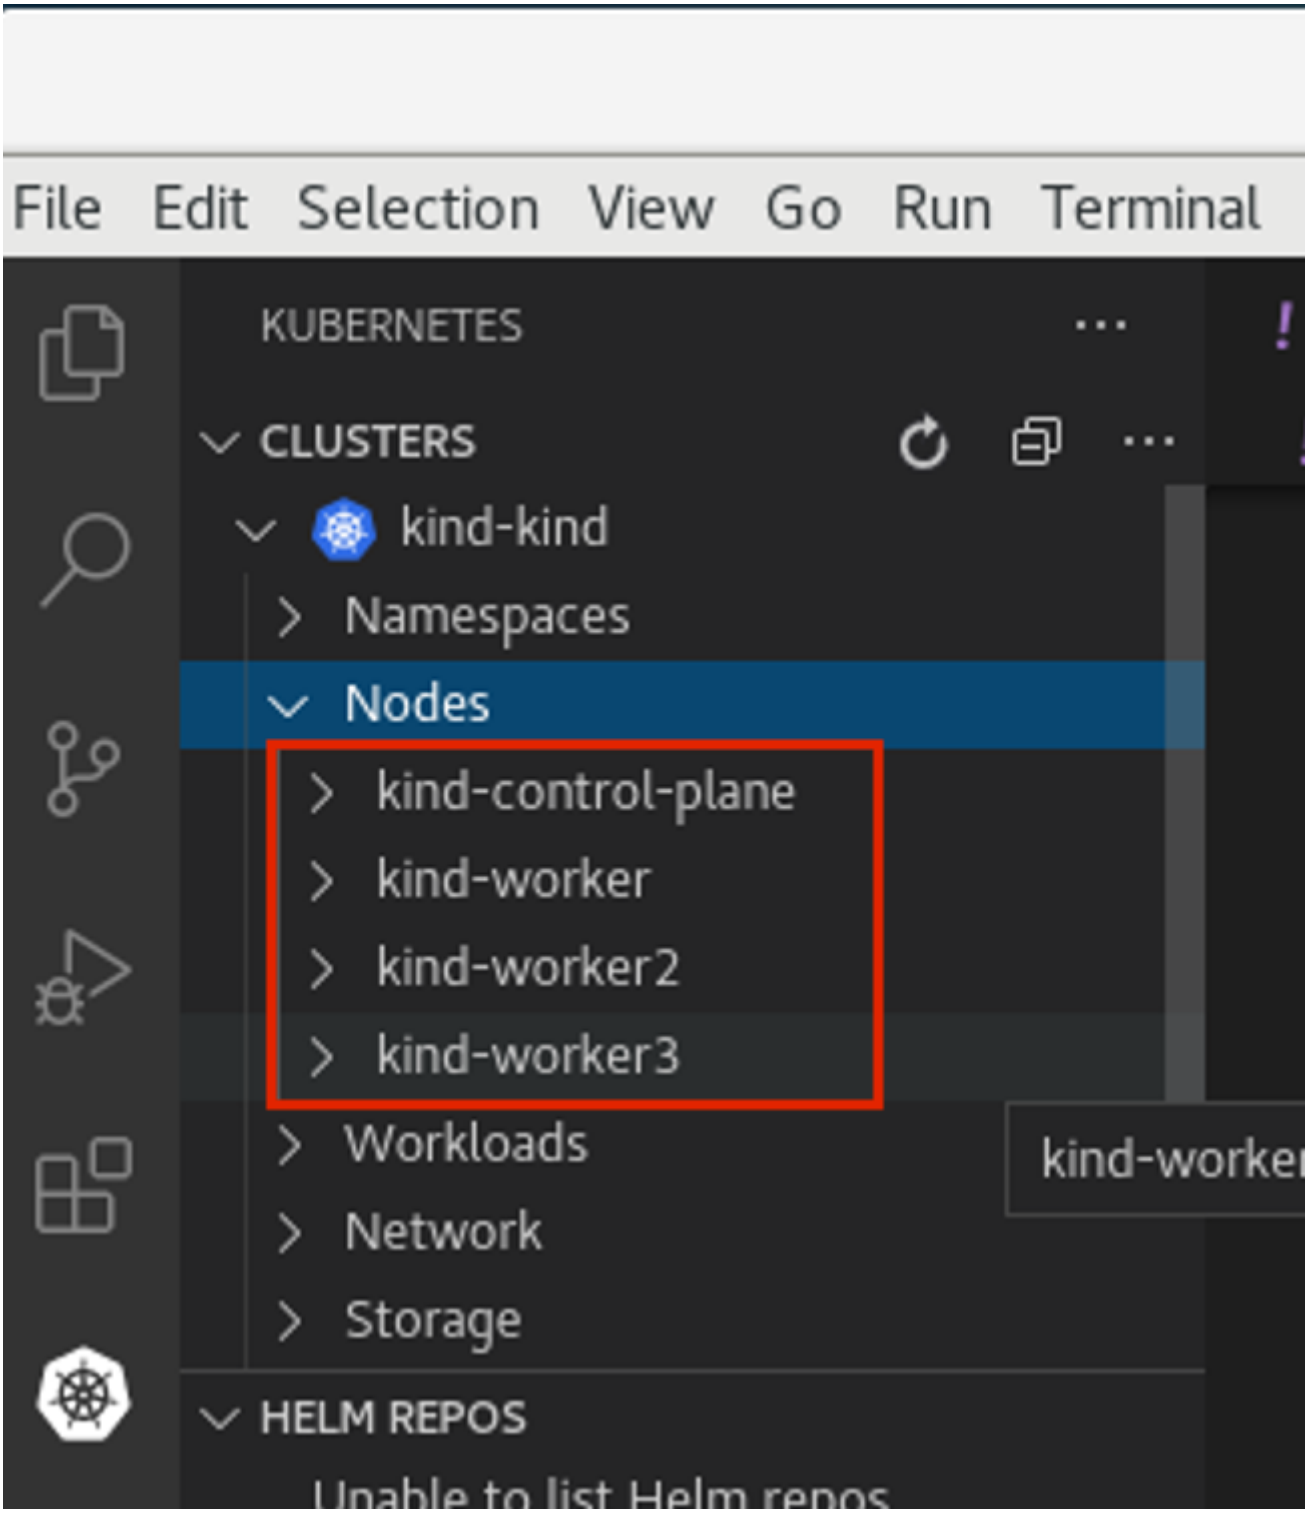
: file name too long
```

Let’s check the vscode kube cluster window we will see the nodes there let’s verify them with the cli

Open vscode, from the cli type **code**, Since this is an overview, we are not going to use VSCode that much, just wanted to share so you could take advantage of the great plugin offered within the VSCode community.



```
  kubeclt get nodes
```

OUTPUT:

```
NAME                 STATUS   ROLES                  AGE     VERSION
kind-control-plane   Ready    control-plane,master   7m14s   v1.20.2
kind-worker          Ready    <none>                 6m45s   v1.20.2
kind-worker2         Ready    <none>                 6m46s   v1.20.2
kind-worker3         Ready    <none>                 6m46s   v1.20.2
```

Build a frontend using wordpress and backend using mysql

Luckily, there is an official tutorial which is pretty well described. We can try most steps of it using kind cluster which we just created. Kubernetes Docs

We will create 3 files and add the following data.

First we make a dir/folder

```
mkdir k8folder
```

We will cd into the folder k8folder before we do the next steps.

You can copy and paste it, which creates a secret and sets a password to f5demo.

```
 cat <<EOF >./kustomization.yaml
secretGenerator:
- name: mysql-pass
  literals:
  - password=f5demo
EOF
```

OUTPUT:

```
 cat kustomization.yaml
secretGenerator:
- name: mysql-pass
  literals:
  - password=f5demo
```

Now we will get the mysql deployment, the curl will save the file locally.

```
 curl -LO https://k8s.io/examples/application/wordpress/mysql-deployment.yaml
```

OUTPUT:

```
 curl -LO https://k8s.io/examples/application/wordpress/mysql-deployment.yaml
  % Total    % Received % Xferd  Average Speed   Time    Time     Time  Current
                                 Dload  Upload   Total   Spent    Left  Speed
100   178  100   178    0     0    751      0 --:--:-- --:--:-- --:--:--   751
100  1193  100  1193    0     0   2475      0 --:--:-- --:--:-- --:--:-- 17289
```

READ mysql deployment file

```
 cat mysql-deployment.yaml
apiVersion: v1
kind: Service
metadata:
  name: wordpress-mysql
  labels:
    app: wordpress
spec:
  ports:
    - port: 3306
  selector:
    app: wordpress
    tier: mysql
  clusterIP: None
---
apiVersion: v1
kind: PersistentVolumeClaim
metadata:
  name: mysql-pv-claim
  labels:
    app: wordpress
spec:
  accessModes:
    - ReadWriteOnce
  resources:
    requests:
      storage: 20Gi
---
apiVersion: apps/v1
kind: Deployment
metadata:
  name: wordpress-mysql
  labels:
    app: wordpress
spec:
  selector:
    matchLabels:
      app: wordpress
      tier: mysql
  strategy:
    type: Recreate
  template:
    metadata:
      labels:
        app: wordpress
        tier: mysql
    spec:
      containers:
      - image: mysql:5.6
        name: mysql
        env:
```

```
        - name: MYSQL_ROOT_PASSWORD
          valueFrom:
            secretKeyRef:
              name: mysql-pass
              key: password
        ports:
        - containerPort: 3306
          name: mysql
        volumeMounts:
        - name: mysql-persistent-storage
          mountPath: /var/lib/mysql
      volumes:
      - name: mysql-persistent-storage
        persistentVolumeClaim:
          claimName: mysql-pv-claim
```

We notice the version of MySQL as well as the key for the password. In addition we will be able to see the port used by the container.

We will now get the wordpress deployment as well, using curl.

```
 curl -LO https://k8s.io/examples/application/wordpress/wordpress-deployment.yaml
```

OUTPUT:

```
 curl -LO https://k8s.io/examples/application/wordpress/wordpress-deployment.yaml
  % Total    % Received % Xferd  Average Speed   Time    Time     Time  Current
                                 Dload  Upload   Total   Spent    Left  Speed
100   178  100   178    0     0   2022      0 --:--:-- --:--:-- --:--:--  2000
100  1278  100  1278    0     0   7139      0 --:--:-- --:--:-- --:--:--  7139
```

READ wordpress deployment file

```

          name: wordpress
        volumeMounts:
        - name: wordpress-persistent-storage
          mountPath: /var/www/html
      volumes:
      - name: wordpress-persistent-storage
```

```
        persistentVolumeClaim:
          claimName: wp-pv-claim
```

As well as mysql, we can see which port is used and which image is going to be launched for the frontend wordpress.

As we have downloaded the two files for our deployment, we will now add the resources into our original file called kustomization. The following data will be appended.

```
cat <<EOF >>./kustomization.yaml
resources:
  - mysql-deployment.yaml
  - wordpress-deployment.yaml
EOF
```

Let's look how the file is now constructed

```
 cat kustomization.yaml
secretGenerator:
- name: mysql-pass
  literals:
  - password=f5demo
resources:
  - mysql-deployment.yaml
  - wordpress-deployment.yaml
```

As we have all our files and configuration we will execute them using the kubectl command to start the deployment. Instead of running each command separately, we will leverage the flag -k.

NOTE	from the help the -k shows us the following: -k, --kustomize='': Process a kustomization directory. This flag can't be used together with -f or -R. --openapi -patch=true: If true, use openapi to calculate diff when the openapi presents and the resource can be found in the openapi spec. Otherwise, fall back to use baked-in types.

```
kubectl apply -k ./
```

OUTPUT:

```
 kubectl apply -k .
secret/mysql-pass-7564dm6k4b created
service/wordpress-mysql created
service/wordpress created
deployment.apps/wordpress-mysql created
deployment.apps/wordpress created
persistentvolumeclaim/mysql-pv-claim created
persistentvolumeclaim/wp-pv-claim created
```

Now let's check the secrets.

```
kubectl get secrets
```

OUTPUT:

```
kubectl get secrets
NAME                  TYPE                                  DATA   AGE
default-token-rkcdp   kubernetes.io/service-account-token   3      22h
mysql-pass-7564dm6k4b   Opaque                                1      79s
```

We want to get a little more information from that, therefore, we will run the describe flag.

```
kubectl describe secrets mysql-pass
```

OUTPUT:

```
 kubectl describe secrets mysql-pass
Name:         mysql-pass-7564dm6k4b
Namespace:    default
Labels:       <none>
Annotations:  <none>

Type:  Opaque

Data
====
password:  6 bytes
```

We do however want to understand storage used on the container we built with K8s. If you scroll up you will see the reference Volumes and the name used for that container. Therefore, we want to check that out.

```
kubectl get pvc
```

OUTPUT:

```
 kubectl get pvc
NAME             STATUS   VOLUME                                     CAPACITY   ACCESS
MODES   STORAGECLASS   AGE
mysql-pv-claim   Bound    pvc-c60d5c62-23a8-4866-a2ac-2ce4c0577c8f   20Gi       RWO
standard       8m6s
wp-pv-claim      Bound    pvc-1266556a-8cad-4afb-821c-aa94f780b9f5   20Gi       RWO
standard       8m6s
```

As we can see the name matches with what's in the describe.

As we have started our deployment, now let's check our pods. The second command is giving you the exact output of the first, however, less typing.

```
kubectl get pods (full)
kubectl get po
```

We want to use services in K8s for many reason we have discussed during our presentation, now let's check them.

```
kubectl get services <name of the services>
kubectl get svc <name of the services >
```

OUTPUT:

```
kubectl get svc
NAME              TYPE           CLUSTER-IP     EXTERNAL-IP   PORT(S)        AGE
kubernetes        ClusterIP      10.96.0.1      <none>        443/TCP        22h
wordpress         LoadBalancer   10.96.212.79   <pending>     80:30782/TCP   12m
wordpress-mysql   ClusterIP      None           <none>        3306/TCP       12m
```

The above command shows you what's in the default namespace, if you want or need to check out a specific namespace, then you can use the -A option or -n follow by the namespace name. Furthermore,

OUTPUT -A

```
 kubectl get svc -A
NAMESPACE     NAME              TYPE           CLUSTER-IP     EXTERNAL-IP   PORT(S)
AGE
default       kubernetes        ClusterIP      10.96.0.1      <none>        443/TCP
22h
default       wordpress         LoadBalancer   10.96.212.79   <pending>
80:30782/TCP             12m
default       wordpress-mysql   ClusterIP      None           <none>        3306/TCP
12m
kube-system   kube-dns          ClusterIP      10.96.0.10     <none>
53/UDP,53/TCP,9153/TCP   22h
```

Endpoints are important and therefore we want to get as much data as possible. Example: (ip addresses of the pods)

```
kubectl get endpoints
```

OUTPUT:

```
 kubectl get endpoints
NAME              ENDPOINTS         AGE
kubernetes        172.18.0.4:6443   22h
wordpress         10.244.1.3:80     15m
wordpress-mysql   10.244.3.3:3306   15m
```

If we are looking at this, we can detect that each node has it's block, 10.244.1.x for pod 3, 10.244.3.x for pod 2 etc.

To make sure that's the case, let's check to confirm

```
 kubectl describe node kind-worker2
Name:               kind-worker2
Roles:              <none>
Labels:             beta.kubernetes.io/arch=amd64

```

NOTE Check the cidr for that node.

Now we are at the final steps to access our application. As we have talked, there are 3 type in Kubernetes which allows you to access the container. One is NodePort, (not suggested for produciton), default is ClusterIP, which allows communication between the pods, and the last one is LoadBalancer, but we do not have an IPAM which gives us an IP address. Therefore, we will use port-forward to test the application we just span up.

```
kubectl port-forward svc/wordpress 8000:80
```

OUTPUT:

```
kubectl port-forward svc/wordpress 8000:80
Forwarding from 127.0.0.1:8000 -> 80
Forwarding from [::1]:8000 -> 80
```

NOTE do not break out from the terminal otherwise you will not be able to access the application. Open a new terminal.

As we have a MySQL container, and we know there is a password we set let's evaluate the pod. Find the password from the container info

```
kubectl describe po wordpress-mysql (look for the MYSQL_ROOT_PASSWORD).
```

OUTPUT:

```
 kubectl describe po wordpress-mysql
Name:         wordpress-mysql-dd6c4c7c9-mkxfp
```

```
Namespace:    default

```

Now let's open firefox and go to

```
localhost:8000
```

Spend a few min configuring your new application.

Optional Lab,
to see how scale works we will start with one and then scale up and down.

Scale example:
Run a new deployment

```
kubectl create deployment grey --image=itlinux/httpd_grey
```

OUTPUT:

```
kubectl get deploy
NAME              READY   UP-TO-DATE   AVAILABLE   AGE
grey              1/1     1            0           13s
wordpress         1/1     1            1           36m
wordpress-mysql   1/1     1            1           36m
```

Now let's levarage help

```
kubectl scale -h
```

OUTPUT:

```
 kubectl scale -h
Set a new size for a Deployment, ReplicaSet, Replication Controller, or StatefulSet.

 Scale also allows users to specify one or more preconditions for the scale action.
```

```
 If --current-replicas or --resource-version is specified, it is validated before the
scale is attempted, and it is
guaranteed that the precondition holds true when the scale is sent to the server.

Examples:
  # Scale a replicaset named 'foo' to 3.
  kubectl scale --replicas=3 rs/foo

  # Scale a resource identified by type and name specified in "foo.yaml" to 3.
  kubectl scale --replicas=3 -f foo.yaml

  # If the deployment named mysql's current size is 2, scale mysql to 3.
  kubectl scale --current-replicas=2 --replicas=3 deployment/mysql

  # Scale multiple replication controllers.
  kubectl scale --replicas=5 rc/foo rc/bar rc/baz

  # Scale statefulset named 'web' to 3.
  kubectl scale --replicas=3 statefulset/web

Options:
      --all=false: Select all resources in the namespace of the specified resource
types
      --allow-missing-template-keys=true: If true, ignore any errors in templates when
a field or map key is missing in
the template. Only applies to golang and jsonpath output formats.
      --current-replicas=-1: Precondition for current size. Requires that the current
size of the resource match this
value in order to scale.
      --dry-run='none': Must be "none", "server", or "client". If client strategy,
only print the object that would be
sent, without sending it. If server strategy, submit server-side request without
persisting the resource.
  -f, --filename=[]: Filename, directory, or URL to files identifying the resource to
set a new size
  -k, --kustomize='': Process the kustomization directory. This flag can't be used
together with -f or -R.
  -o, --output='': Output format. One of:
json|yaml|name|go-template|go-template-file|template|templatefile|jsonpath|jsonpath-
as-json|jsonpath-file.
      --record=false: Record current kubectl command in the resource annotation. If
set to false, do not record the
command. If set to true, record the command. If not set, default to updating the
existing annotation value only if one
already exists.
  -R, --recursive=false: Process the directory used in -f, --filename recursively.
Useful when you want to manage
related manifests organized within the same directory.
      --replicas=0: The new desired number of replicas. Required.
      --resource-version='': Precondition for resource version. Requires that the
```

```
current resource version match this
value in order to scale.
  -l, --selector='': Selector (label query) to filter on, supports '=', '==', and
'!='.(e.g. -l key1=value1,key2=value2)
      --template='': Template string or path to template file to use when -o=go
-template, -o=go-template-file. The
template format is golang templates [http://golang.org/pkg/text/template/#pkg-
overview].
      --timeout=0s: The length of time to wait before giving up on a scale operation,
zero means don't wait. Any other
values should contain a corresponding time unit (e.g. 1s, 2m, 3h).

Usage:
  kubectl scale [--resource-version=version] [--current-replicas=count]
--replicas=COUNT (-f FILENAME | TYPE NAME)
[options]

Use "kubectl options" for a list of global command-line options (applies to all
commands).
```

We notice in the Examples a scale for the deployment. Therefore, we will use a similar one, but first let's check our pods.

Pods

```
 kubectl get pods
NAME                              READY   STATUS    RESTARTS   AGE
grey-664f87894f-zr52n             1/1     Running   0          3m12s
wordpress-9f58bb5bc-pdn7r         1/1     Running   0          39m
wordpress-mysql-dd6c4c7c9-mkxfp   1/1     Running   0          39m
```

We do see there is only one grey pod. Now let's scale up. But before we scale let's make sure we can access the new container.

```
kubectl port-forward deployment/grey 8222:80
```

Open firefox at

```
localhost:8222
```

Scale our Pod

```
 kubectl scale --current-replicas=1 --replicas=3 deployment/grey
```

Now let's check pods again. .Pods

```
 kubectl get pods
NAME                              READY   STATUS    RESTARTS   AGE
grey-664f87894f-542xl             1/1     Running   0          13s
grey-664f87894f-8wvm5             1/1     Running   0          13s
grey-664f87894f-zr52n             1/1     Running   0          4m54s
wordpress-9f58bb5bc-pdn7r         1/1     Running   0          41m
wordpress-mysql-dd6c4c7c9-mkxfp   1/1     Running   0          41m
```

As well as we scaled up we can now scale down. Similar command.

```
 kubectl scale --current-replicas=3 --replicas=1 deployment/grey
```

OUTPUT:

```
 kubectl get pods
NAME                              READY   STATUS        RESTARTS   AGE
grey-664f87894f-542xl             1/1     Running       0          2m13s
grey-664f87894f-8wvm5             1/1     Terminating   0          2m13s
grey-664f87894f-zr52n             1/1     Terminating   0          6m54s
wordpress-9f58bb5bc-pdn7r         1/1     Running       0          43m
wordpress-mysql-dd6c4c7c9-mkxfp   1/1     Running       0          43m
```

NOTE your application still runs :) even when we scaled down.

If we want to access a specific worker node where the app is running for the grey app, you can use the following as an example, your id maybe diff:

```
kubectl port-forward grey-5794d7f866-w8t98 8088:80
```

This ends the lab.
Thanks
