### **Kubernetes - Workshop**

This is just an intro, which tights to the presentation of Modern Application. For this workshop we will leverage kind.

Kind is a tool for running local Kubernetes clusters using Docker container "nodes". kind was primarily designed for testing Kubernetes itself, but may be used for local development or CI.

We will first build a simple cluster with a specific name. If you omit the flag --name default name will be kind. As we get a little more familiar with kind cli, keep in mind that the other tool we could have selected was minikube, however, kind is newer and allows you to run a small kubernetes cluster for testing and learning purposes.

#### Shotcut your typing

```
echo "alias k=kubectl" >>~/.bashrc
kubectl completion bash|sed 's/kubectl/k/g' >>.bashrc
. .bashrc
```

Understand how to use help with kubectl. Each main subcommand has a subset of help. The main will be kubectl -h or kubectl --help. Of course, this workshop is not going through each of the commands, that's something you can explore in your own. We will however cover many of them.

Show Merged kubeconfig settings.

```
kubectl config view
```

Use multiple kubeconfig files at the same time and view merged config

```
KUBECONFIG=~/.kube/config:~/.kube/kubconfig2
```

```
kubectl config view
```

Display list of contexts

```
kubectl config get-contexts
```

Display the current-context

```
kubectl config current-context
```

Set the default context to my-cluster-name, the name can be showed with the command above.

```
kubectl config use-context <<cluster-name>>
kubectl config set-context kind-remo
kubectl config -h <to get some additional help>
```

EXAMPLE: (in my case I have two running, KIND and Minikube, and it shows you which is the default config)

```
kubectl config get-contexts
CURRENT NAME CLUSTER AUTHINFO NAMESPACE
* kind-kind kind-kind
minikube minikube minikube default
```

Add a new user to your kubeconf that supports basic auth. We use this example in our Agility Lab, which was offered the last couple of years. CIS Lab

```
kubectl config set-credentials kubeuser/foo.kubernetes.com --username=kubeuser
--password=kubepassword
```

Permanently save the namespace for all subsequent kubectl commands in that context.

```
kubectl config set-context --current --namespace=ciao
```

Set a context utilizing a specific username and namespace.

```
kubectl config set-context gce --user=cluster-admin --namespace=ciao \
&& kubectl config use-context gce
```

This unsets the config for the user ciao kubectl config unset users.ciao

## Single Cluster

First let's evaluate kind's help

```
kind --help
kind creates and manages local Kubernetes clusters using Docker container 'nodes'
Usage:
 kind [command]
Available Commands:
 build
             Build one of [node-image]
 completion Output shell completion code for the specified shell (bash, zsh or fish)
 create Creates one of [cluster]
 delete
             Deletes one of [cluster]
 export
             Exports one of [kubeconfig, logs]
             Gets one of [clusters, nodes, kubeconfig]
 get
             Help about any command
 help
             Loads images into nodes
 load
             Prints the kind CLI version
 version
Flags:
 -h, --help
                         help for kind
     --loglevel string DEPRECATED: see -v instead
                         silence all stderr output
 -q, --quiet
 -v, --verbosity int32 info log verbosity
     --version
                  version for kind
Use "kind [command] --help" for more information about a command.
```

```
kind create cluster --name workshop
```

#### **OUTPUT:**

```
B kind create cluster --name workshop
Creating cluster "workshop" ...
Bensuring node image (kindest/node:v1.20.2) B
Preparing nodes B
Writing configuration B
Starting control-plane B
Installing CNI B
Installing StorageClass B
Set kubectl context to "kind-workshop"
You can now use your cluster with:
kubectl cluster-info --context kind-workshop
Have a nice day! B
```

Using kind command to verify we have a cluster

l kind get clusters **OUTPUT:** b kind get clusters workshop Check nodes b kubectl get nodes OUTPUT: We can see the workshop name for the control plane. l k get nodes NAMF STATUS **ROLES** AGE **VERSION** workshop-control-plane Ready control-plane, master 11m v1.20.2 We will use the describe subcommand to see the details of the node. L kubectl describe no <<your node name>> Example: ubect describe no workshop-control-plane **NOTE** the option no is short for nodes. **OUTPUT:** ubectl describe no workshop-control-plane Name: workshop-control-plane Roles: control-plane, master beta.kubernetes.io/arch=amd64 Labels: beta.kubernetes.io/os=linux kubernetes.io/arch=amd64 kubernetes.io/hostname=workshop-control-plane kubernetes.io/os=linux node-role.kubernetes.io/control-plane= node-role.kubernetes.io/master= Annotations: kubeadm.alpha.kubernetes.io/cri-socket: unix:///run/containerd/containerd.sock node.alpha.kubernetes.io/ttl: 0 volumes.kubernetes.io/controller-managed-attach-detach: true

```
read-only: cannot modify conntrack limits, problems may arise later (If running Docker, see docker issue #24000)

Normal Starting 24m kube-proxy Starting kube-proxy.

Normal NodeReady 24m kubelet Node workshop-control-plane status is now: NodeReady
```

Delete the current kind cluster. If you have the default cluster, named **kind**, you do not have to use the --name option.

```
kind delete cluster --name workshop
```

#### **OUTPUT:**

```
B kind delete cluster --name workshop
Deleting cluster "workshop" ...
```

Create a cluster with 3 workers. create a file, called mykind with the directions below:

```
🛮 vi mykind
```

Directives for the file mykind. This will build the control plane and 3 workers node.

```
kind: Cluster
apiVersion: kind.x-k8s.io/v1alpha4
# One control plane node and three "workers".
#
# While these will not add more real compute capacity and
# have limited isolation, this can be useful for testing
# rolling updates etc.
#
# The API-server and other control plane components will be
# on the control-plane node.
#
# You probably don't need this unless you are testing Kubernetes itself.
nodes:
- role: control-plane
- role: worker
- role: worker
```

To build the new cluster with 3 workers and 1 control-plane execute the following:

```
kind create cluster --config mykind
```

#### OUTPUT:

```
B kind create cluster --config mykind
Creating cluster "kind" ...
B Ensuring node image (kindest/node:v1.20.2) B
Preparing nodes B B B B
Writing configuration B
Starting control-plane BB
Installing CNI B
Installing StorageClass B
Joining worker nodes B
Set kubectl context to "kind-kind"
You can now use your cluster with:
kubectl cluster-info --context kind-kind
Thanks for using kind! B
```

#### Check nodes

```
L kubectl get nodes
```

OUTPUT: We can see the workshop name for the control plane.

```
l k get nodes
NAME
                     STATUS
                                                     AGE
                                                             VERSION
                              ROLES
kind-control-plane
                              control-plane, master
                                                             v1.20.2
                     Ready
                                                     2m35s
kind-worker
                     Ready
                                                     2m4s
                                                             v1.20.2
                              <none>
kind-worker2
                     Ready
                                                     2m4s
                                                             v1.20.2
                              <none>
kind-worker3
                                                             v1.20.2
                     Ready
                                                     2m4s
                              <none>
```

#### OUTPUT: with the wide option

As you recall from our docker section, we will check how many containers are running in docker.

```
    docker ps
```

#### **OUTPUT:**

<pre>docker ps</pre>				
CONTAINER ID	IMAGE	COMMAND	CREATED	STATUS
PORTS	NAMES			
4edfee1fd18f	kindest/node:v1.20.2	"/usr/local/bin/entr…"	3 minutes ago	Up 3
minutes 127.	0.0.1:54190->6443/tcp	kind-control-plane

# Let's check the vscode kube cluster window we will see the nodes there let's verify them with the cli

Open vscode, from the cli type **code**, Since this is an overview, we are not going to use VSCode that much, just wanted to share so you could take advantage of the great plugin offered within the VSCode community.

## Edit Selection View Go Run Terminal File KUBERNETES ✓ CLUSTERS 🐯 kind-kind Namespaces Nodes kind-control-plane kind-worker kind-worker2 > kind-worker3 Workloads kind-worker Network Storage ✓ HELM REPOS Inable to list Helm repos

b kubeclt get nodes

#### **OUTPUT:**

	ROLES AGE VERSION control-plane, master 7m14s v1.20.2 <none> 6m45s v1.20.2 <none> 6m46s v1.20.2 <none> 0m46s v1.20.2</none></none></none>	STATUS Ready Ready Ready Ready	NAME kind-control-plane kind-worker kind-worker2 kind-worker3
--	---	--	---

## Build a frontend using wordpress and backend using mysql

Luckily, there is an official tutorial which is pretty well described. We can try most steps of it using kind cluster which we just created. Kubernetes Docs

We will create 3 files and add the following data.

First we make a dir/folder

```
mkdir k8folder
```

We will cd into the folder k8folder before we do the next steps.

You can copy and paste it, which creates a secret and sets a password to f5demo.

```
cat <<EOF >./kustomization.yaml
secretGenerator:
- name: mysql-pass
  literals:
  - password=f5demo
EOF
```

#### **OUTPUT:**

```
cat kustomization.yaml
secretGenerator:
- name: mysql-pass
  literals:
  - password=f5demo
```

Now we will get the mysql deployment, the curl will save the file locally.

```
curl -LO https://k8s.io/examples/application/wordpress/mysql-deployment.yaml
```

#### **OUTPUT:**

```
url -LO https://k8s.io/examples/application/wordpress/mysql-deployment.yaml

                                    0 --:--:- 17289
```

READ mysql deployment file

```
cat mysql-deployment.yaml
apiVersion: v1
kind: Service
metadata:
  name: wordpress-mysql
  labels:
    app: wordpress
spec:
  ports:
    - port: 3306
  selector:
    app: wordpress
    tier: mysql
  clusterIP: None
apiVersion: v1
kind: PersistentVolumeClaim
metadata:
  name: mysql-pv-claim
  labels:
    app: wordpress
spec:
  accessModes:
    - ReadWriteOnce
  resources:
    requests:
      storage: 20Gi
apiVersion: apps/v1
kind: Deployment
metadata:
  name: wordpress-mysql
  labels:
    app: wordpress
spec:
  selector:
    matchLabels:
      app: wordpress
      tier: mysql
  strategy:
    type: Recreate
  template:
    metadata:
      labels:
        app: wordpress
        tier: mysql
    spec:
      containers:
      - image: mysql:5.6
        name: mysql
        env:
```

```
- name: MYSQL_ROOT_PASSWORD
    valueFrom:
        secretKeyRef:
        name: mysql-pass
        key: password
ports:
    - containerPort: 3306
    name: mysql
    volumeMounts:
    - name: mysql-persistent-storage
        mountPath: /var/lib/mysql
volumes:
    - name: mysql-persistent-storage
    persistentVolumeClaim:
        claimName: mysql-pv-claim
```

We notice the version of MySQL as well as the key for the password. In addition we will be able to see the port used by the container.

We will now get the wordpress deployment as well, using curl.

```
□ curl -LO https://k8s.io/examples/application/wordpress/wordpress-deployment.yaml
```

#### **OUTPUT:**

```
□ curl -LO https://k8s.io/examples/application/wordpress/wordpress-deployment.yaml

      - image: wordpress:4.8-apache
        name: wordpress
        env:
        - name: WORDPRESS_DB_HOST
          value: wordpress-mysql
        - name: WORDPRESS_DB_PASSWORD
          valueFrom:
            secretKeyRef:
              name: mysql-pass
              key: password
        ports:
        - containerPort: 80
          name: wordpress
        volumeMounts:
        - name: wordpress-persistent-storage
          mountPath: /var/www/html
      volumes:
      - name: wordpress-persistent-storage
```

```
persistentVolumeClaim:
claimName: wp-pv-claim
```

As well as mysql, we can see which port is used and which image is going to be launched for the frontend wordpress.

As we have downloaded the two files for our deployment, we will now add the resources into our original file called kustomization. The following data will be appended.

```
cat <<EOF >>./kustomization.yaml
resources:
   - mysql-deployment.yaml
   - wordpress-deployment.yaml
EOF
```

Let's look how the file is now constructed

```
cat kustomization.yaml
secretGenerator:
- name: mysql-pass
  literals:
  - password=f5demo
resources:
  - mysql-deployment.yaml
  - wordpress-deployment.yaml
```

As we have all our files and configuration we will execute them using the kubectl command to start the deployment. Instead of running each command separately, we will leverage the flag -k.

NOTE

from the help the -k shows us the following: -k, --kustomize=": Process a kustomization directory. This flag can't be used together with -f or -R. --openapi -patch=true: If true, use openapi to calculate diff when the openapi presents and the resource can be found in the openapi spec. Otherwise, fall back to use baked-in types.

```
kubectl apply -k ./
```

**OUTPUT:** 

```
l kubectl apply -k .
secret/mysql-pass-7564dm6k4b created
service/wordpress-mysql created
service/wordpress created
deployment.apps/wordpress-mysql created
deployment.apps/wordpress created
persistentvolumeclaim/mysql-pv-claim created
persistentvolumeclaim/wp-pv-claim created
```

Now let's check the secrets.

```
kubectl get secrets
```

#### **OUTPUT:**

```
kubectl get secrets

NAME TYPE DATA AGE

default-token-rkcdp kubernetes.io/service-account-token 3 22h

mysql-pass-7564dm6k4b Opaque 1 79s
```

We want to get a little more information from that, therefore, we will run the describe flag.

```
kubectl describe secrets mysql-pass
```

#### **OUTPUT:**

Labels: <none>
Annotations: <none>

Type: Opaque

Data ====

password: 6 bytes

We do however want to understand storage used on the container we built with K8s. If you scroll up you will see the reference Volumes and the name used for that container. Therefore, we want to check that out.

```
kubectl get pvc
```

#### OUTPUT:

```
l kubectl get pvc
NAME
                 STATUS
                         VOLUME
                                                                     CAPACITY
                                                                               ACCESS
MODES
        STORAGECLASS
                     AGE
                                                                                RWO
mysql-pv-claim Bound
                         pvc-c60d5c62-23a8-4866-a2ac-2ce4c0577c8f
                                                                    20Gi
               8m6s
standard
                                                                                RWO
wp-pv-claim
                 Bound
                          pvc-1266556a-8cad-4afb-821c-aa94f780b9f5
                                                                    20Gi
standard
               8m6s
```

As we can see the name matches with what's in the describe.

As we have started our deployment, now let's check our pods. The second command is giving you the exact output of the first, however, less typing.

```
kubectl get pods (full)
kubectl get po
```

We want to use services in K8s for many reason we have discussed during our presentation, now let's check them.

```
kubectl get services <name of the services>
kubectl get svc <name of the services >
```

#### **OUTPUT:**

kubectl get svc  NAME TYPE kubernetes ClusterIP wordpress LoadBalancer wordpress-mysql ClusterIP	CLUSTER-IP EXTERNATION	> 443/TCP 22h ing> 80:30782/TCP 12m	
--	------------------------	--	--

The above command shows you what's in the default namespace, if you want or need to check out a specific namespace, then you can use the -A option or -n follow by the namespace name. Furthermore,

#### **OUTPUT-A**

] kubectl get NAMESPACE	NAME	TYPE	CLUSTER-IP	EXTERNAL-IP	PORT(S)
NAMESPACE AGE	NAME	ITPE	CLUSIEK-1P	EXICKNAL-1P	PURI(3)
AOC default	kubernetes	ClusterIP	10.96.0.1	<00000\	443/TCP
22h	Kubernetes	Clustelly	10.30.0.1	<none></none>	443/ TCP
default	wordpress	LoadBalancer	10.96.212.79	<pending></pending>	
30:30782/TCP	12m				
default	wordpress-mysql	ClusterIP	None	<none></none>	3306/TCP
12m					
cube-system	kube-dns	ClusterIP	10.96.0.10	<none></none>	
53/UDP,53/TCP	,9153/TCP 22h				

Endpoints are important and therefore we want to get as much data as possible. Example: (ip addresses of the pods)

```
kubectl get endpoints
```

#### **OUTPUT:**

```
NAME ENDPOINTS AGE kubernetes 172.18.0.4:6443 22h wordpress 10.244.1.3:80 15m wordpress-mysql 10.244.3.3:3306 15m
```

If we are looking at this, we can detect that each node has it's block, 10.244.1.x for pod 3, 10.244.3.x for pod 2 etc.

To make sure that's the case, let's check to confirm

kubernetes.io/arch=amd64
kubernetes.io/hostname=kind-worker2

kubernetes.io/os=linux

```

**NOTE** Check the cidr for that node.

Now we are at the final steps to access our application. As we have talked, there are 3 type in Kubernetes which allows you to access the container. One is NodePort, (not suggested for produciton), default is ClusterIP, which allows communication between the pods, and the last one is LoadBalancer, but we do not have an IPAM which gives us an IP address. Therefore, we will use port-forward to test the application we just span up.

```
kubectl port-forward svc/wordpress 8000:80
```

#### **OUTPUT:**

```
kubectl port-forward svc/wordpress 8000:80
Forwarding from 127.0.0.1:8000 -> 80
Forwarding from [::1]:8000 -> 80
```

NOTE

do not break out from the terminal otherwise you will not be able to access the application. Open a new terminal.

As we have a MySQL container, and we know there is a password we set let's evaluate the pod. Find the password from the container info

```
kubectl describe po wordpress-mysql (look for the MYSQL_ROOT_PASSWORD).
```

#### **OUTPUT**:

```
l kubectl describe po wordpress-mysql
Name: wordpress-mysql-dd6c4c7c9-mkxfp
```

Namespace: default Priority: Node: kind-worker2/172.18.0.3 Start Time: Fri, 14 May 2021 11:00:05 -0700 app=wordpress Labels: pod-template-hash=dd6c4c7c9 tier=mysql Annotations: <none> Running Status: IP: 10.244.3.3 IPs: 10.244.3.3 IP: Controlled By: ReplicaSet/wordpress-mysql-dd6c4c7c9 Containers: mysql: Container ID: containerd://ca5c4a78d86a36a220aaf6c16e5e3af762b25d03ebd56f6633dfb80bba237d91 Image: mysq1:5.6 Image ID: docker.io/library/mysql@sha256:1d96ea86f9173607f1534c05041bf18dba691ded86d2ab51f6fd453 3377fac39 Port: 3306/TCP Host Port: 0/TCP State: Running Started: Fri, 14 May 2021 11:00:15 -0700 Ready: True Restart Count: 0 Environment: MYSQL\_ROOT\_PASSWORD: <set to the key 'password' in secret 'mysql-pass-7564dm6k4b'> Optional: false Mounts: /var/lib/mysql from mysql-persistent-storage (rw) /var/run/secrets/kubernetes.io/serviceaccount from default-token-rkcdp (ro) Conditions: Status Type Initialized True True Ready ContainersReady True PodScheduled True Volumes: mysql-persistent-storage: PersistentVolumeClaim (a reference to a PersistentVolumeClaim in the Type: same namespace) ClaimName: mysql-pv-claim ReadOnly: false default-token-rkcdp: Secret (a volume populated by a Secret) Type: SecretName: default-token-rkcdp Optional: false QoS Class: BestEffort Node-Selectors: <none>

Now let's open firefox and go to

```
localhost:8000
```

Spend a few min configuring your new application.

#### Optional Lab,

to see how scale works we will start with one and then scale up and down.

Scale example:

Run a new deployment

```
kubectl create deployment grey --image=itlinux/httpd_grey
```

#### **OUTPUT:**

kubectl get depl	Uy			
NAME	READY	UP-TO-DATE	AVAILABLE	AGE
grey	1/1	1	0	13s
wordpress	1/1	1	1	36m
wordpress-mysql	1/1	1	1	36m

Now let's levarage help

```
kubectl scale -h
```

#### **OUTPUT:**

L kubectl scale -h
Set a new size for a Deployment, ReplicaSet, Replication Controller, or StatefulSet.
Scale also allows users to specify one or more preconditions for the scale action.

If --current-replicas or --resource-version is specified, it is validated before the scale is attempted, and it is guaranteed that the precondition holds true when the scale is sent to the server. Examples: # Scale a replicaset named 'foo' to 3. kubectl scale --replicas=3 rs/foo # Scale a resource identified by type and name specified in "foo.yaml" to 3. kubectl scale --replicas=3 -f foo.yaml # If the deployment named mysql's current size is 2, scale mysql to 3. kubectl scale --current-replicas=2 --replicas=3 deployment/mysql # Scale multiple replication controllers. kubectl scale --replicas=5 rc/foo rc/bar rc/baz # Scale statefulset named 'web' to 3. kubectl scale --replicas=3 statefulset/web Options: --all=false: Select all resources in the namespace of the specified resource --allow-missing-template-keys=true: If true, ignore any errors in templates when a field or map key is missing in the template. Only applies to golang and isonpath output formats. --current-replicas=-1: Precondition for current size. Requires that the current size of the resource match this value in order to scale. --dry-run='none': Must be "none", "server", or "client". If client strategy, only print the object that would be sent, without sending it. If server strategy, submit server-side request without persisting the resource. -f, --filename=[]: Filename, directory, or URL to files identifying the resource to set a new size -k, --kustomize='': Process the kustomization directory. This flag can't be used together with -f or -R. -o, --output='': Output format. One of: json|yaml|name|go-template|go-template-file|template|templatefile|jsonpath|jsonpathas-json|jsonpath-file. --record=false: Record current kubectl command in the resource annotation. If set to false, do not record the command. If set to true, record the command. If not set, default to updating the existing annotation value only if one already exists. -R, --recursive=false: Process the directory used in -f, --filename recursively. Useful when you want to manage related manifests organized within the same directory. --replicas=0: The new desired number of replicas. Required.

--resource-version='': Precondition for resource version. Requires that the

```
current resource version match this
value in order to scale.
  -l, --selector='': Selector (label query) to filter on, supports '=', '==', and
'!='.(e.g. -l key1=value1,key2=value2)
      --template='': Template string or path to template file to use when -o=go
-template, -o=go-template-file. The
template format is golang templates [http://golang.org/pkg/text/template/#pkg-
overview].
      --timeout=0s: The length of time to wait before giving up on a scale operation,
zero means don't wait. Any other
values should contain a corresponding time unit (e.g. 1s, 2m, 3h).
Usage:
  kubectl scale [--resource-version=version] [--current-replicas=count]
--replicas=COUNT (-f FILENAME | TYPE NAME)
[options]
Use "kubectl options" for a list of global command-line options (applies to all
commands).
```

We notice in the Examples a scale for the deployment. Therefore, we will use a similar one, but first let's check our pods.

#### Pods

```
□ kubectl get pods
NAME
                                  READY
                                          STATUS
                                                    RESTARTS
                                                                AGE
grey-664f87894f-zr52n
                                                                3m12s
                                  1/1

                                          Running
                                  1/1
                                                                39m
```

We do see there is only one grey pod. Now let's scale up. But before we scale let's make sure we can access the new container.

```
kubectl port-forward deployment/grey 8222:80
```

Open firefox at

```
localhost:8222
```

Scale our Pod

```
u kubectl scale --current-replicas=1 --replicas=3 deployment/grey
```

Now let's check pods again. .Pods

```
l kubectl get pods
                                           STATUS
                                                     RESTARTS
NAME
                                   READY
                                                                 AGE
grey-664f87894f-542xl
                                           Running
                                   1/1
                                                                 13s
grey-664f87894f-8wvm5
                                   1/1
                                           Running
                                                                 13s
                                                                 4m54s
grey-664f87894f-zr52n
                                   1/1
                                           Running
                                                      0
wordpress-9f58bb5bc-pdn7r
                                   1/1
                                           Running
                                                                 41m
wordpress-mysql-dd6c4c7c9-mkxfp
                                           Running
                                                                 41m
                                   1/1
                                                      0
```

As well as we scaled up we can now scale down. Similar command.

```
b kubectl scale --current-replicas=3 --replicas=1 deployment/grey
```

#### OUTPUT:

<pre>b kubectl get pods</pre>				
NAME	READY	STATUS	RESTARTS	AGE
grey-664f87894f-542xl	1/1	Running	0	2m13s
grey-664f87894f-8wvm5	1/1	Terminating	0	2m13s
grey-664f87894f-zr52n	1/1	Terminating	0	6m54s
wordpress-9f58bb5bc-pdn7r	1/1	Running	0	43m
wordpress-mysql-dd6c4c7c9-mkxfp	1/1	Running	0	43m

**NOTE** your application still runs :) even when we scaled down.

If we want to access a specific worker node where the app is running for the grey app, you can use the following as an example, your id maybe diff:

```
kubectl port-forward grey-5794d7f866-w8t98 8088:80
```

This ends the lab.

Thanks
